1. GENERAL

1.01 This section provides procedures for diagnosing and clearing malfunctions in the maintenance data transmitter (MDT). Detailed procedures for clearing trouble in the programmable scanner distributor are given in Section 190-107-301.

1.02 This section is reissued for the following reasons:

(a) To add table of contents

(b) To add paragraphs on trouble identification, trouble isolation, MDT interaction with the marker group, and MDT initialization.

2. TROUBLE IDENTIFICATION

2.01 MDT trouble indications are indicated to maintenance personnel in the following ways:

(a) Trouble message printouts at the end office keyboard printer and at the automatic trouble analysis (ATA) administration terminal

(b) LED displays at the PSD control panel

(c) Fuse alarm LED

(d) Audible major alarms

(e) Symptoms indicating that ATA is not functioning correctly for a particular end office but no other trouble indicators are present.

Trouble indications a and d are covered in Section 190-107-301 which contains flowcharts to aid in trouble locating and correcting hard faults for these trouble categories. Trouble indications b, c, and e are covered in this section.

Typical symptoms of trouble indication e include excessive garbage cards, punching nonexpress cards when the MDT mode is set for transmit only for nonexpress cards, missing time line printouts, and inability to get a response from central when using the keyboard printer to request information.

2.02 No. 5 crossbar trouble location and correction requires some knowledge of circuit operation, some indications of what circuit is failing, where in the sequence of operation it is failing, and some means for testing that circuit to reproduce the trouble.

2.03 There are three areas of MDT operation for which additional trouble locating procedures are provided in this section. The first area is
isolating the problem to the end office, data link, or ATA central. The second area is the external interfacing between the central office and the MDT. The third area is locating a hard fault in the MDT when circuit pack replacement does not correct the problem.

3. TROUBLE CLEARING

3.01 MDT trouble clearing consists of trouble message, initialization, and fatal error procedures.

3.02 Insert a busy plug in the MDTMB jack at the master test frame connector (MTFC) before starting trouble clearing procedures. Remove the plug after the trouble is cleared.

3.03 Block the LMJ relay nonoperated before performing trouble clearing procedures in Section 190-107-301. Remove blocking tool after trouble is cleared.

3.04 If the FA LED on the control panel is lighted, replace the blown fuse. If the fuse blows again, refer to Section 190-107-301. There are two fuses at the base of the frame for the 132H converter and the interface unit.

3.05 If a trouble message has been received at the printer, proceed to Fig. 1. If no trouble message is present, observe the LEDs on the control panel and proceed to Fig. 2.

3.06 The trouble clearing procedures are presented in flowchart form.

4. TROUBLE ISOLATION

4.01 Trouble could result from problems in the MDT/central office, the data link, or the central computer.

A. Switching Control Center (SCC) Keyboard Printer

4.02 Verify that the data link is good in both directions between the central office and computer.

B. SCC

4.03 Verify that the logger, TTY, and queue are turned on by using the interrogate command.

If any of the three are off, use the restore command to turn them on.

4.04 Set the data set at the end office to test mode. This causes messages from the computer to be looped back through the end office data set and returned to the computer.

4.05 Use the mdt:smode command to change the MDT mode. The mdt:sitename:smode:punch_all:xmit:all command is sent to the data link and looped back to central. After central receives the message, it compares the new mode with the previous mode. A verification is then printed at the SCC keyboard printer. If no response is printed, there is a problem with the computer or data link. No response could also indicate that the computer did not send the message, the data link was bad in either direction, or the computer did not receive the looped back response.

C. Central Computer

4.06 Connect a keyboard printer to the DJ11 or DH11 line for the end office with a null modem cable. The keyboard printer simulates an end office and can then transmit and receive messages to and from the central computer. Type an ! and the central computer responds with an invalid keyword.

4.07 If the ATA system is working correctly, a RUTR message sent to central from the simulated site appears at the SCC keyboard printer as an MDT status change. The RUTR message format from the simulated end office would be (CNTR-A) F @ @ C A (CR).

D. Central Office

4.08 A keyboard printer can be used to simulate the ATA central at an MDT end office. The data link cable is removed from I/O port 0 or 1 and a keyboard printer is connected through a null modem cable to I/O port 0 or 1.

4.09 If a spare keyboard printer is used to simulate an ATA central, the regular keyboard printer remains connected to I/O port 2. The two keyboard printers are used to send and receive information.

4.10 If a spare keyboard printer is not available, remove the regular keyboard printer from
I/O port 2 and connect to I/O port 0 or 1 to simulate the ATA central. The simulated ATA central cannot verify the ability to transmit messages to I/O port 2 but can be used to set or clear distribute points, change MDT mode, etc.

5. MDT INTERACTION WITH THE MARKER GROUP

5.01 The basic circuitry necessary for the MDT to obtain trouble record information is shown in Fig. 3. Fig. 4 is a flowchart that can be used to locate troubles and correct hard faults.

5.02 When a circuit requesting a trouble record gets preference in the MTFC, the connector grounds the STR lead (nonexpress service type troubles) or the STRA lead (express test circuit type troubles). If the MDT is in service to trouble record cards (MB relay normal), the STR or STRA scan point (SP) will recognize this ground. The MDT determines what the mode is for that particular type of request. The mode indicates if the trouble record is to be transmitted to the ATA central, to be punched at the trouble recorder, or both.

5.03 If the trouble record is to be transmitted to ATA central, the MDT does a prescan of the MTFC scanning relays. It prescans by operating the S8, SA8, R8, and RA8 scan relays first. It reads the information passed through these relays to the trouble recorder on the BW(000-119) and BWX(0-4) leads. The S8, SA8, R8, and RA8 relays are released. The S7, SA7, R7, and RA7 relays are then operated and the next line of information is read from the BW000-119 leads. This action continues until the SO row has been read. The S0 relays are then released. The MDT determines if the mode requires a card to be punched on site. If a card is required to be punched, the MDT grounds its TRC DP. This grounds the TRC lead to the trouble recorder. The trouble recorder causes a card to be perforated. The prescan starts with S8 and scans down to S0 but the trouble recorder perforates by starting with S0 and scanning up to S8.

5.04 If the trouble record is not required to be perforated, the MDT grounds its TRC DP. This grounds the TRC lead to the trouble recorder. This lead multiplies the TRC contact in the trouble recorder and causes the TRC relay in the MTFC to operate and release the call. The STR or STRA lead is opened, removing the ground start to the MDT. The MDT recognizes the removal and releases its TRC DP. It is then ready for the next trouble record.

5.05 If a trouble record was perforated, the trouble recorder operates its TRC relay. The operation of the TRC relay causes the MTFC to remove ground from the STR or STRA start leads. The MDT recognizes the removal and subsequently releases its STR or STRA DP and releases the STR1 or STR2 relay in the trouble recorder. This restores the trouble recorder to normal.

5.06 The typical troubles that can occur in the MDT are shown in Table A with the probable cause.

5.07 MDT detected troubles are transmitted to the computer in the form of trouble messages. The trouble messages are shown in Table B with the probable cause.

5.08 The MDT distribute points, STR, STRA, TRC, S(0-8), are connected to the central office through contacts of the MB relay. Any crosses on those contacts can result in trouble messages being printed.

5.09 A cross between STRA and S8 leads results in mutilated trouble record information because the S8 relay is held operated for the whole prescan cycle and through the punch cycle if a card is to be punched.

6. INITIALIZATION

6.01 Figure 5 shows the flowchart for initialization. When the MDT power is turned on or the initialization switch is operated, the MDT will initialize. A pulse is generated internally on the reset lead which causes the procon to restart the read only memory (ROM) program. The operation of the LMJ relay in the MDT will also force the procon to reinitialize.

6.02 When a trouble is encountered during initialization, the sanity timer times out and causes the LMJ relay to operate. This starts the initialization routine again to release the LMJ relay. This action results in the LMJ relay pulsing. If the LMJ relay is operated continuously (not pulsing), it indicates that the automatic reinitialization feature is failing. Possible causes are open or grounded.
RST/RST leads or a bad trouble indication (TBI) circuit pack (FB597). The reset lead could also be open between the MDT and the procon. If operation of the INIT switch causes the procon to reinitialize, then the trouble is between the LMJ relay contact and the INIT switch contacts. If a momentary ground placed on the reset lead (pin 206) of the TBI circuit pack causes the procon to reinitialize, then the problem is between the TBI circuit pack and the LMJ relay.

6.03 The flowchart (Fig. 5) indicates which lamp indications are set when a failure is encountered. There is a possibility that when the LMJ relay is not causing reinitialization, the lamp display is random. The reinitialization problem must be cleared first.

6.04 Most initialization problems occur because of a bad TBI circuit pack, an MB scan point problem, or I/O 0 or 1 data port not operational.

MAINTENANCE DATA TRANSMITTER
TROUBLE-LOCATING PROCEDURE
NO. 5 CROSSBAR

1. GENERAL

1.001 This addendum supplements Section 190-106-301, Issue 2. Place this pink sheet ahead of Page 1 of the section.

1.002 This addendum is reissued to add a maintenance data transmitter (MDT) log (Fig. 1.1).

2. CHANGES TO SECTION

2.001 On Page 2, revise paragraph 3.05 as follows:
If a trouble message has been received at the printer, proceed to Fig. 1. If no MDT trouble message is present, observe and record the programmable scanner distributor (PSD) control panel light-emitting diodes (LEDs) on the MDT log (Fig. 1.1), then proceed to Fig. 2 for troubleshooting procedures.
ATA SITE ________________________________

STEPS
1. LOG ALL DISPLAYS ON THIS SHEET.
2. PUSH "EX" (EXTINGUISH) BUTTON.
3. IF DISPLAY DOES NOT EXTINGUISH, REFER TO FIG. 2 OF SECTION 190-106-301.
4. IF STEP 3 DOES NOT CLEAR TROUBLE, REFER TO SWITCHING CONTROL CENTER.
